Phishing attacks are an ongoing threat to information security. Unlike hardware or network based attacks, phishing attacks rely on users’ susceptibilities. By following a link to a phishing website users can unknowingly send personal information to an attacker. The consequences of sending personal information can result in significant financial losses. Mobile devices (phones, tablets, etc.) are presenting unique challenges to detecting whether a link or message is a phishing attack. Together, we will investigate best practices for detecting a phishing attack on a mobile device and education methods for users. http://users.ipfw.edu/parkermc/
